**Fact Sheet**

**Basic Farriery and Foot Balance**

The modern horse we know today has evolved over millions of years, surviving quite happily without human intervention with regards to hoof maintenance. In a natural environment, horses graze varied terrain, wearing away the excess hoof growth to keep the hoof at a constant length without the need for trimming or shoeing.

Horses are now bred for performance and the way in which the modern equine is maintained and managed means that hoof care and maintenance is very important in ensuring soundness and performance. A well balanced foot will be symmetrical in size and shape and land flat on the ground (figure 1).

**Foot conformation**

The hoof is made up of many tiny tubes (called horn tubules) that, when packed together, form a very strong horny capsule around a similarly shaped bone inside, which is attached to the rest of the skeleton.

A horse’s conformation is such that from the fetlock down, the limb is projected forward, along with the hoof capsule and not straight down like a post.

This means that as the hoof grows longer it also grows more forward, thus increasing the overall length from the fetlock (figure 2). Significant increases in length and/or distortion of the foot shape can result in lameness both from within the hoof and structures further up the limb. Regular trimming and correction of distortions is vitally important for maintaining soundness.

**Routine farriery**

The majority of horses working on the roads or hard ground will require shoeing. The use of shoes helps to reduce the rate of hoof wear and improve comfort levels. The shoe also helps improve grip on wet or slippery surfaces and assists in stabilising the hoof to prevent splits or cracks forming.

Routine farriery is the trimming and shoeing of the sound horse with a normal foot. This should be done every 4 – 6 weeks. Shoes can be applied hot or cold, but the hot method is preferred as more accurate shaping of the shoe can be carried out. A range of specialist shoes are available and can be used to manage certain conditions. Pads and packing materials can also be used under the shoe to improve foot comfort for horses doing long distances or with sensitive feet.

**KEY POINTS**

- All domestic horses and ponies require regular foot trimming to prevent hoof distortion and lameness.
- The majority of horses doing a significant amount of work on hard ground will require shoeing.
- Trimming and shoeing should be carried out by a qualified farrier.
- A well balanced foot will be symmetrical in size and shape and land flat during movement.

**Foot balance – front to back**

This should be assessed from the side on a level surface. The foot should be aligned so that the hoof-pastern axis forms an unbroken line when viewed from the side (figure 3).

A long toe/low heel conformation increases the loading on the back of the foot, predisposing the horse to pain, inflammation and damage to the navicular bone and supporting structures. Excessive wear of the toe, in association with increased heel length will result in an upright, boxy hoof capsule, leading to conditions such as a club foot.

**FOOT BALANCE – SIDE TO SIDE**

Also known as medio-lateral balance, this refers to the relative symmetry of the foot and should be assessed by viewing the foot from in front and behind, as well as from above with the foot lifted up.

Medio-lateral imbalance (figures 4 and 5) leads to uneven loading of the internal tissues of the foot, with the resultant accumulation of damage, causing inflammation, injury and lameness.

X-ray examination

X-ray examination can help determine the relative positions of the pedal bone and hoof wall and assess shoe placement (Figure 6).

To find a suitably qualified farrier in your area visit the farrier registration council website:

**KEY POINTS**

- Don’t panic! Choke is rarely life-threatening and many cases will resolve spontaneously.
- Seek veterinary advice if the choke lasts more than 30 minutes and while waiting for the vet remove all food to prevent your horse eating and worsening the obstruction.
- Following an episode of choke it is worth monitoring your horse’s respiratory rate (normal <16 breaths/min) and rectal temperature for several days.
- Arrange regular dental check-ups for your horse to reduce the risk of choke as a result of a painful mouth.

**Clinical signs:**

- difficulty/repeated attempts at swallowing
- stretching/arching of the neck
- coughing
- food & saliva discharging from the nose
- drooling
- disinterest in food
- occasionally a lump may be seen or felt on the left side of the neck.

If you suspect your horse is suffering from choke it is important to prevent your horse eating as this will make the blockage worse and more difficult to clear.

If the obstruction doesn’t clear quickly of its own accord then veterinary assistance must be sought. There are a number of steps your vet can take to help to confirm and treat the problem.

Horses and ponies with dental problems (that prevent them grinding their food properly), individuals that bolt their food too quickly and those fed dry pelleted or cubed feeds are all at increased risk.

**REGULAR DENTAL EXAMINATIONS AND TREATMENT CAN REDUCE THE RISK OF CHOKE**
